
Postgraduate Certificate in Shipping Decarbonization Strategies

Ship Design for Low-Carbon Performance

Absorption Chiller – A cooling system that uses heat energy, often from waste heat or renewable sources, to produce chilled water. Related: waste heat recovery, refrigerant cycle. Example: integrating an absorption chiller with a LNG-fueled ship's exhaust heat reduces electrical load. Challenge: limited cooling capacity and larger equipment footprint compared to vapor-compression chillers.

Alternative Fuels – Non-conventional energy carriers such as liquefied natural gas (LNG), methanol, ammonia, hydrogen, and bio-fuels. Related: fuel flexibility, carbon intensity. Example: a container vessel designed for dual-fuel capability can switch between LNG and low-sulphur fuel oil. Challenge: fuel availability, storage safety, and infrastructure compatibility.

Aerodynamic Hull Form – Hull shapes optimized to reduce air resistance, especially for vessels with significant above-water structures. Related: wind resistance, superstructure design. Example: a cruise ship with a streamlined superstructure and reduced deck clutter experiences lower wind-induced drag. Challenge: balancing aesthetic, passenger space, and structural requirements.

Ballast Water Management – Systems that treat ballast water to meet environmental regulations while minimizing energy use. Related: BWMS, energy recovery. Example: using low-energy UV treatment paired with recirculation pumps that draw power from renewable sources. Challenge: ensuring compliance without excessive power draw.

Barometric Pressure Compensation – Adjusting propulsion system performance based on atmospheric pressure to maintain optimal efficiency. Related: engine tuning, sensor integration. Example: a diesel engine control unit that reduces fuel injection rate at high altitude ports. Challenge: accurate real-time data and integration with existing control logic.

Beam-to-Length Ratio – The proportion of a ship's beam (width) to its length, influencing resistance and stability. Related: slenderness ratio, hull efficiency. Example: a slender container ship (beam-to-length ratio ~0.12) achieves lower wave resistance. Challenge: maintaining adequate cargo capacity and transverse stability.

Bow Thruster Optimization – Design and control strategies that minimize energy consumption of bow thrusters during maneuvering. Related: dynamic positioning, thrust allocation. Example: variable-frequency drives combined with predictive control reduce thruster power by up to 30 %. Challenge: ensuring sufficient maneuverability in confined ports.

Carbon Capture on Board – Technologies that capture CO₂ emissions from exhaust gases for storage or utilization while at sea. Related: CCS, emissions reduction. Example: a pilot project using amine-based

scrubbers on a research vessel. Challenge: added weight, space constraints, and high energy penalty.

Carbon Intensity Rating – A metric that quantifies CO₂ emissions per cargo unit (e.g., grams CO₂ per tonne-km). Related: IMO EEXI, SEEMP. Example: a liner service targeting a 15 % reduction in carbon intensity over five years. Challenge: accurate data collection across varied routes and fuel types.

Center of Gravity Management – Controlling the vertical and longitudinal position of the ship's centre of gravity to enhance stability and reduce resistance. Related: ballast distribution, weight optimization. Example: using lightweight composite decks to lower the vertical centre of gravity. Challenge: retrofitting existing vessels without compromising structural integrity.

Clean Propulsion Systems – Propulsion technologies that emit little or no greenhouse gases, such as electric motors, fuel cells, or hybrid diesel-electric arrangements. Related: zero-emission, hybridization. Example: a short-sea ferry powered by lithium-ion batteries for port operations. Challenge: limited energy density and the need for shore-side charging infrastructure.

Co-generation (CHP) – Simultaneous production of electricity and useful heat from a single fuel source, improving overall energy efficiency. Related: waste heat recovery, thermal management. Example: a ship's diesel engine driving an alternator that supplies shipboard power while capturing exhaust heat for water heating. Challenge: matching heat demand with production and integrating with other energy systems.

Computational Fluid Dynamics (CFD) – Numerical simulation tools used to predict flow patterns around hulls, propellers, and appendages. Related: hydrodynamic analysis, virtual prototyping. Example: CFD-optimised bulbous bow reduces wave resistance by 5 % in sea trials. Challenge: high computational cost and the need for validation with physical model tests.

Conceptual Design Phase – The early stage where overall ship architecture, performance targets, and feasibility are defined. Related: preliminary sizing, trade-off studies. Example: selecting a hybrid propulsion layout based on route analysis and emission caps. Challenge: limited data on future fuel availability and regulatory changes.

Cooling Load Management – Strategies to balance cooling demand with available energy, often using heat recovery and smart controls. Related: HVAC optimization, thermal storage. Example: using chilled water produced by an absorption chiller during night-time low-load periods. Challenge: predicting variable cooling loads in different climate zones.

Deadweight Tonnage (DWT) Optimization – Adjusting payload distribution to maximize cargo while minimizing resistance and fuel consumption. Related: payload planning, trim control. Example: loading heavy containers aft to achieve optimal trim for a voyage. Challenge: operational constraints and port handling limitations.

Deck Layout Integration – Designing deck structures to accommodate low-carbon technologies without

compromising cargo handling or passenger comfort. Related: space allocation, modular design. Example: placing battery modules beneath deck plates to preserve cargo space. Challenge: ensuring structural strength and fire safety compliance.

Drag-Reducing Coatings – Specialized hull paints that lower frictional resistance through micro-textured surfaces or polymer additives. Related: fouling control, surface roughness. Example: a silicone-based coating achieving a 3 % drag reduction in long-haul service. Challenge: durability, cost, and compatibility with anti-fouling requirements.

Dynamic Positioning (DP) Energy Efficiency – Optimizing DP system algorithms to reduce power consumption while maintaining vessel position. Related: thruster control, power management. Example: using model-predictive control to anticipate wind drift and adjust thruster output pre-emptively. Challenge: maintaining reliability under extreme weather conditions.

Electric Propulsion – Use of electric motors to drive propellers, often powered by generators or batteries. Related: motor sizing, power electronics. Example: a Ro-Ro ferry equipped with a permanent-magnet motor delivering 8 MW of thrust. Challenge: thermal management of power electronics and integration with existing fuel systems.

Emissions Trading Scheme (ETS) – Market-based mechanism that caps total emissions and allows trading of allowances. Related: carbon credits, compliance strategy. Example: a shipping company purchasing allowances to offset emissions from high-fuel-consumption routes. Challenge: price volatility and regulatory uncertainty.

Energy Management System (EMS) – Integrated software that monitors, analyses, and optimises energy flows across all ship systems. Related: data analytics, predictive maintenance. Example: EMS automatically throttles auxiliary generators when battery SOC (state of charge) exceeds 80 %. Challenge: ensuring cybersecurity and interoperability with legacy equipment.

Energy-Efficient Hull Form – Hull shapes designed to minimise total resistance, including wave, viscous, and wind components. Related: slender hull, bulbous bow. Example: a fully-flooded bulbous bow tuned for a 15 kt service speed reduces fuel consumption by 4 %. Challenge: cost of redesign and validation for multiple operating speeds.

Environmental Performance Index (EPI) – Composite score that rates a vessel's environmental impact based on emissions, waste, and noise. Related: sustainability metrics, stakeholder reporting. Example: a ship achieving an EPI of 85 % qualifies for green port incentives. Challenge: aligning diverse metrics into a single actionable index.

Exhaust Gas Recirculation (EGR) – Technique that re-injects a portion of exhaust gases into the combustion chamber to lower peak temperatures and NO_x formation. Related: emissions control, engine tuning. Example: a dual-fuel engine using EGR to meet IMO Tier III NO_x limits. Challenge: managing soot buildup

and maintaining combustion efficiency.

Fifth-Generation (5G) Connectivity – High-speed, low-latency communication networks enabling real-time data exchange for ship performance monitoring. Related: IoT, remote diagnostics. Example: transmitting propulsion performance metrics to shore-based analysts for immediate optimisation. Challenge: coverage in remote oceanic regions and data security.

Fouling Management Strategy – Integrated approach combining anti-fouling coatings, regular cleaning, and hull-form design to limit bio-fouling growth. Related: drag reduction, maintenance scheduling. Example: using a low-toxicity silicone coating combined with periodic in-water cleaning reduces fuel use by 2%. Challenge: balancing environmental compliance with cleaning frequency.

Fuel Cell Power Plant – Electrochemical devices that convert hydrogen or other fuels directly into electricity with high efficiency and zero tailpipe emissions. Related: PEM fuel cell, solid-oxide fuel cell. Example: a research vessel employing a 2 MW PEM fuel cell for propulsion. Challenge: hydrogen storage safety, durability under marine conditions, and high initial capital cost.

Fuel Flexibility Design – Architectural provisions that allow a ship to operate on multiple fuel types without major modifications. Related: dual-fuel engines, fuel switching. Example: a container ship equipped with LNG tanks, methanol storage, and a compatible engine. Challenge: space allocation, weight distribution, and certification for each fuel.

Fuel Sulphur Content Regulation – Limits set by IMO (currently 0.5% globally) on the sulphur percentage in marine fuels to reduce SOx emissions. Related: scrubbers, low-sulphur fuel oil. Example: installing exhaust gas cleaning systems to allow the use of higher-sulphur fuel in emission-control areas. Challenge: additional capital cost and maintenance of scrubbers.

Frictional Resistance Reduction – Techniques aimed at lowering the viscous drag component of total resistance. Related: laminar flow promotion, hull smoothing. Example: applying a low-roughness polymer coating that decreases skin friction by 7% in trials. Challenge: long-term coating durability and compatibility with cleaning regimes.

Forward-Looking Energy Assessment – Predictive analysis that estimates future energy demand based on projected routes, fuel prices, and regulatory trends. Related: scenario planning, lifecycle costing. Example: modelling a 20-year fleet upgrade path to meet the 2030 carbon cap. Challenge: uncertainties in technology adoption rates and policy changes.

Gas Turbine Propulsion – Utilisation of gas turbines, often in combined cycle configurations, for ship propulsion. Related: COGES, hybrid propulsion. Example: a high-speed ferry using a gas turbine driving a water-jet for rapid acceleration. Challenge: high fuel consumption at low loads and limited fuel flexibility.

Global Wind Atlas Integration – Leveraging wind resource data to design and position auxiliary sails or

rotors for energy harvesting. Related: sail-assisted propulsion, renewable integration. Example: installing a rigid-sail system on a bulk carrier that captures prevailing westerly winds. Challenge: impact on vessel stability and cargo operations.

Green Ship Rating – Classification society certification that recognises vessels designed with superior environmental performance. Related: DNV Green Ship, Lloyd's Register Eco-Design. Example: a container ship receiving a Green Ship award for meeting stringent CO₂ reduction targets. Challenge: meeting the rating criteria while staying cost-effective.

Hybrid Energy Storage – Combination of batteries, supercapacitors, and flywheels to provide flexible power for propulsion and auxiliary loads. Related: power management, peak shaving. Example: a hybrid system that uses supercapacitors for rapid load changes during docking. Challenge: complex control algorithms and lifecycle management of multiple storage technologies.

Hydrodynamic Appendage Optimization – Design of rudders, thrusters, and stabilisers to minimise added resistance while preserving functionality. Related: vortex shedding control, CFD analysis. Example: a semi-balanced rudder with a streamlined profile reduces drag by 1.5 %. Challenge: ensuring adequate manoeuvrability under varied sea states.

Hydrogen Fuel Infrastructure – Shore-side facilities for storage, transfer, and refuelling of hydrogen to support marine operations. Related: bunkering, safety protocols. Example: a port installing cryogenic hydrogen tanks and a dedicated bunkering berth for fuel-cell vessels. Challenge: high capital investment and regulatory approval.

Hydrogen Production Pathways – Methods for generating hydrogen, such as electrolysis (green), steam-methane reforming (grey), or biomass gasification (blue). Related: carbon capture, renewable electricity. Example: a shipping line sourcing green hydrogen from offshore wind-powered electrolyzers. Challenge: scaling production to meet maritime demand at competitive cost.

Hydrodynamic Shape Optimization – Use of parametric modelling and optimisation algorithms to refine hull geometry for minimal resistance. Related: genetic algorithms, surrogate modelling. Example: applying a multi-objective optimisation that balances fuel efficiency with cargo volume. Challenge: computational expense and translating virtual results to physical hull forms.

Ice-Class Design for Low-Carbon Vessels – Structural and propulsion considerations for ships operating in polar regions while maintaining low emissions. Related: reinforced hull, hybrid propulsion. Example: an ice-strengthened LNG carrier equipped with a battery-assisted propulsion system to meet emission limits in the Arctic. Challenge: added weight of ice reinforcement and limited battery performance in low temperatures.

Impact Assessment of Emission Zones – Evaluation of how Emission Control Areas (ECAs) affect ship routes, fuel choice, and overall carbon footprint. Related: routing software, compliance cost. Example: modelling

alternative routes to avoid EU ECAs, resulting in a 5 % increase in voyage distance but a 12 % reduction in SOx emissions. Challenge: balancing economic penalties with environmental benefits.

Integrated Bridge-Engine Room (IBER) – Consolidated control architecture that merges navigation and propulsion systems for coordinated operation. Related: automation, crew training. Example: an IBER system that automatically adjusts propeller pitch based on heading changes to minimise energy waste. Challenge: ensuring redundancy and crew familiarity with integrated interfaces.

Intelligent Propeller Pitch Control – Adaptive adjustment of propeller pitch in real-time to maintain optimal thrust efficiency across varying speeds. Related: controllable-pitch propeller, sensor fusion. Example: a controllable-pitch propeller that reduces fuel consumption by 3 % during speed fluctuations in congested waterways. Challenge: mechanical complexity and maintenance of pitch mechanisms.

Lifecycle Carbon Accounting – Comprehensive accounting of CO₂ emissions from material extraction, construction, operation, and disposal of a vessel. Related: embodied carbon, operational emissions. Example: assessing that 30 % of a ship's total carbon footprint originates from steel production, prompting material substitution. Challenge: data availability and standardisation across supply chains.

Low-Carbon Material Substitution – Replacing traditional steel components with lighter, lower-embodied-carbon alternatives such as aluminium alloys or fibre-reinforced polymers. Related: weight reduction, structural integrity. Example: using aluminium for deck superstructures reduces overall vessel weight by 8 %, improving fuel efficiency. Challenge: cost, corrosion resistance, and fire safety compliance.

Marine Renewable Energy Integration – Incorporation of on-board renewable sources such as solar panels, wind turbines, or wave energy converters. Related: auxiliary power, energy harvesting. Example: a solar array covering 1 000 m² of deck area supplying 150 kW to shipboard loads. Challenge: limited surface area, variability of generation, and added weight.

Modular Ship Design – Construction approach where ship sections are built as interchangeable modules, facilitating upgrades and retrofits for low-carbon technologies. Related: plug-and-play, future-proofing. Example: a modular battery block that can be replaced with a larger unit as energy density improves. Challenge: ensuring structural continuity and certification of modular interfaces.

Multi-Fuel Engine Certification – Process of obtaining regulatory approval for engines capable of operating on several fuel types while meeting emission standards. Related: type approval, performance testing. Example: a dual-fuel engine certified for LNG, methanol, and diesel, allowing flexible operation based on fuel availability. Challenge: extensive testing and documentation for each fuel scenario.

Naval Architecture Trade-Off Analysis – Systematic evaluation of conflicting design objectives such as cargo capacity, speed, and emissions. Related: Pareto frontier, decision matrix. Example: using a weighted scoring model to select a hull form that balances a 0.5 % speed loss with a 10 % fuel saving. Challenge: quantifying intangible factors like crew comfort.

Noise and Vibration Control – Measures to reduce acoustic emissions, which indirectly affect fuel consumption by improving propeller-wake interaction. Related: acoustic insulation, propeller design. Example: installing flexible mounts for auxiliary generators reduces transmitted vibrations, leading to smoother hull flow. Challenge: space for damping materials and maintaining accessibility for maintenance.

Optimised Trim and Draft Management – Continuous adjustment of a vessel's longitudinal balance and immersion depth to achieve minimal resistance. Related: ballast optimisation, auto-trim systems. Example: an auto-trim system that shifts ballast water forward during heavy weather to lower wave resistance. Challenge: real-time sensor accuracy and integration with propulsion control.

Passive Aerodynamic Devices – Fixed structures such as fins or spoilers that modify airflow over the ship to reduce wind resistance without active power consumption. Related: wind-drag reduction, superstructure shaping. Example: installing aft-mounted finlets on a Ro-Ro vessel reduces wind-induced fuel penalty by 1 %. Challenge: ensuring they do not interfere with cargo handling or stability.

Petroleum-Based Fuel Alternatives – Low-carbon derivatives of traditional marine fuels, including ultra-low sulphur diesel (ULSD) and synthetic paraffinic kerosene. Related: fuel blending, emissions profile. Example: blending 20 % bio-derived diesel with conventional fuel to achieve a modest carbon reduction. Challenge: fuel compatibility and potential engine wear.

Power-Split Propulsion – Architecture where multiple power sources (e.g., diesel generators, gas turbines, batteries) feed a common electric propulsion motor. Related: hybrid architecture, power management. Example: a power-split system that uses batteries for low-speed maneuvering and diesel generators for cruise operation. Challenge: coordinating power flows and ensuring seamless transition between sources.

Propeller Skew Optimization – Design of propeller blade geometry to spread load over time, reducing cavitation and improving efficiency. Related: cavitation avoidance, thrust ripple. Example: a high-skew propeller on a container ship reduces cavitation erosion and improves fuel efficiency by 2 %. Challenge: manufacturing complexity and cost.

Propulsion System Redundancy Planning – Designing backup propulsion arrangements to maintain operability while pursuing low-carbon goals. Related: fail-safe design, reliability analysis. Example: incorporating an auxiliary diesel engine that can take over if the primary fuel-cell system fails. Challenge: added weight and space for redundant equipment.

Renewable-Based Bunkering – Supplying ships with fuels derived from renewable sources, such as bio-LNG or synthetic e-fuel. Related: green fuel supply chain, certification. Example: a port offering bio-LNG that reduces lifecycle CO₂ emissions by 70 % compared with conventional LNG. Challenge: limited production capacity and price competitiveness.

Retrofit Feasibility Study – Assessment of the technical and economic viability of installing low-carbon technologies on existing vessels. Related: cost-benefit analysis, structural assessment. Example: evaluating

the installation of a battery system on a 20-year-old bulk carrier, identifying a payback period of 7 years. Challenge: limited space and structural reinforcement needs.

Rudder-Propeller Interaction Mitigation – Design techniques to reduce adverse flow effects between the propeller and rudder, improving overall propulsion efficiency. Related: ducted propeller, flow straighteners. Example: adding a flow-straightening strut upstream of the rudder lowers turbulence and improves thrust by 1 %. Challenge: added drag and complexity.

Safety-Critical Energy Systems – Systems whose failure could jeopardise vessel safety, requiring rigorous design and redundancy. Related: fire protection, fault tolerance. Example: incorporating fail-safe controls for battery management to prevent thermal runaway. Challenge: balancing safety margins with weight and cost constraints.

Scrubber Technology Selection – Choosing between open-loop, closed-loop, or hybrid exhaust gas cleaning systems based on fuel type and regulatory zones. Related: discharge permits, water chemistry. Example: a closed-loop scrubber enabling compliance in ports with strict wash-water discharge limits. Challenge: higher capital cost and need for waste disposal.

Sea-State Adaptive Speed Management – Adjusting vessel speed in response to wave conditions to optimise fuel consumption and emissions. Related: weather routing, resistance modelling. Example: reducing speed by 0.5 kn in high sea-state periods to avoid a 5 % fuel penalty. Challenge: meeting schedule commitments while varying speed.

Ship-to-Ship Energy Transfer – Transfer of electrical power between vessels, enabling one ship to supply another's propulsion or hotel loads. Related: high-voltage couplings, marine power grid. Example: a mother vessel providing battery power to a smaller feeder ship during port stay. Challenge: standardising connectors and ensuring safety.

Ship-Scale Energy Modelling – Full-scale simulation of a vessel's energy flows, integrating propulsion, auxiliaries, and environmental loads. Related: system dynamics, digital twin. Example: a digital twin that predicts fuel consumption for different cargo loadings, aiding operational decisions. Challenge: high fidelity data requirements and model validation.

Simplified Energy Index (SEI) – A metric that approximates a ship's energy efficiency based on readily available parameters such as speed, displacement, and engine power. Related: EEDI, SEEMP. Example: using SEI to benchmark a fleet's performance against industry averages. Challenge: limited granularity compared with detailed CFD or trial data.

Smart Battery Management – Advanced control algorithms that optimise charge/discharge cycles, temperature, and health of marine batteries. Related: state-of-charge estimation, predictive maintenance. Example: a BMS that limits depth of discharge to 80 % to extend battery life while meeting peak power demands. Challenge: integrating with shipboard EMS and ensuring reliability under marine conditions.

Slope-Adjusted Hull Coating – Application of coating layers that vary thickness along the hull to balance wear resistance with drag reduction. Related: anti-fouling, coating technology. Example: a thicker coating at the bow where fouling is aggressive and a thinner low-drag coating amidships. Challenge: complex application process and quality control.

Solar-Assisted Propulsion – Use of solar-generated electricity to supplement propulsion power, reducing fuel consumption during daylight operations. Related: photovoltaic panels, power management. Example: a solar-assisted ferry that reduces diesel use by 5 % on sunny routes. Challenge: limited surface area and variability of solar irradiance.

Sustainable Ship Recycling – End-of-life processes that minimise environmental impact, including material recovery and safe disposal of hazardous components. Related: circular economy, ship-breaking standards. Example: designing for dismantling with modular hull plates that can be recycled into new steel. Challenge: compliance with the Hong Kong Convention and economic feasibility.

Thermal Insulation Optimization – Improving insulation of fuel tanks, water lines, and HVAC ducts to reduce heat losses and auxiliary power demand. Related: energy conservation, material selection. Example: installing aerogel blankets around LNG tanks lowers boil-off rates, decreasing fuel consumption for re-liquefaction. Challenge: cost and installation complexity.

Thrust Deduction Factor (t) – Coefficient representing the loss of propulsive thrust due to hull-propeller interaction. Related: propulsive efficiency, wake fraction. Example: a modern hull-propeller arrangement achieving a thrust deduction factor of 0.10, improving overall propulsive efficiency. Challenge: accurate measurement and influence of operating conditions.

Trim Optimization Software – Digital tools that calculate optimal trim settings for varying cargo loads and sea conditions. Related: ballast management, fuel consumption. Example: a software package that suggests a 0.5 m forward trim for a loaded container ship, saving 3 % fuel per voyage. Challenge: integrating with ship's ballast control system.

Ultra-Low-Sulphur Diesel (ULSD) – Marine diesel fuel with sulphur content below 0.1 %, meeting the most stringent emission standards. Related: fuel compliance, engine wear. Example: using ULSD in emission control areas to avoid scrubber installation. Challenge: higher price and limited global availability.

Variable-Frequency Drives (VFD) – Electrical converters that allow motor speed to be adjusted by varying supply frequency, enhancing efficiency. Related: motor control, energy savings. Example: VFDs on auxiliary generators reduce fuel consumption during low-load periods by up to 15 %. Challenge: harmonic distortion and need for robust cooling.

Vessel Energy Management Plan (VEMP) – Structured approach outlining actions, targets, and monitoring procedures to improve a ship's energy performance over its operational life. Related: SEEMP, continuous improvement. Example: a VEMP that sets a 5 % annual fuel reduction target through technology upgrades

and crew training. Challenge: maintaining momentum and verifying results.

Wave-Resistance Minimisation – Design strategies aimed at reducing the energy lost to wave creation, especially at higher speeds. Related: hull form, bulbous bow tuning. Example: a fine-tuned bulbous bow on a cruise ship reduces wave resistance by 4 % at 22 kn. Challenge: optimizing for a range of speeds and loading conditions.

Wind-Assisted Propulsion – Use of sails, kites, or rotor systems to capture wind energy and provide forward thrust, reducing fuel use. Related: Flettner rotor, rigid sail. Example: a 120-meter Flettner rotor installed on a bulk carrier yields a 7 % fuel saving on prevailing westerly routes. Challenge: structural integration, crew training, and variable wind availability.

Zero-Emission Corridor – Designated maritime routes where only zero-carbon vessels are permitted, encouraging adoption of clean technologies. Related: policy incentives, infrastructure. Example: a European North Sea corridor that offers priority docking for battery-powered ferries. Challenge: ensuring sufficient charging infrastructure and vessel availability.

Zero-Carbon Fuel (ZCF) – Fuels that achieve net-zero CO₂ emissions over their lifecycle, such as synthetic e-fuel produced from renewable electricity. Related: carbon accounting, fuel certification. Example: using e-methanol derived from offshore wind to power a chemical tanker, achieving a 95 % reduction in lifecycle emissions. Challenge: high production cost and limited market scale.
